A relative-motion method for parsing spatio-temporal behaviour of dyads using GPS relocation data

Ludovica Luisa Vissat, Jason K. Blackburn and Wayne M. Getz

1. Dyadic analysis

For the dyadic behaviour classification, the procedure (Algorithm 1) is similar to the individual behaviour classification presented in the paper. The difference lies in the fact that we consider the simultaneous individual behaviour, and therefore we have a unique list to keep track of the dyadic behaviour types. This list, indicated by M_D , is composed of n 5-dimensional vectors, initially populated with zeros. The procedure is the same as for the individual classification up to the pair distance calculation. If this distance is below our maximum threshold for considering dyadic interactions, then the function f_{cd} is used to categorise the dyadic behaviour in terms of the angles diffA and diffB and the necessary classification input (i.e. circle segmentation) which we assume implicitly here for the sake of a compact presentation. The update function will then update the list M_D , according to the dyadic behaviour type and the corresponding distance interval.

Algorithm 1: Dyadic behaviour classification

Input $\mathcal{T}_A, \mathcal{T}_B, \mathcal{I}$

$M_D = list()$

for i **in** $\{1, \dots, n\}$ **do**

$M_D[i] = v_0(5)$

$I_{AB} = \mathcal{T}_A \cap \mathcal{T}_B$

for t **in** I_{AB} **do**

 headA = $f(A(t), A(t+1))$, headB = $f(B(t), B(t+1))$

 dirAB = $f(A(t), B(t))$, dirBA = $f(B(t), A(t))$

 diffA = $|headA - dirAB|$, diffB = $|headB - dirBA|$

$d_{AB} = d((A(t), B(t)))$

if $\exists i : d_{AB} \in I_i$ **then**

$m_D = f_{cd}(diffA, diffB)$

$M_D[i] = u(m_D, M_D[i])$

return M_A, M_B

The statistical analysis for the dyadic behaviour, presented in Algorithm 2, requires the list of n vectors M_D as input and uses the entries corresponding to the behaviours of interest for the calculation of the confidence intervals related to each I_i . In this example, we assume these entries are the first four ones, with the fifth one corresponding to the classification “other”. In the algorithm, we use the function `binom.confint` as for the R package `binom`, providing successes, trials, confidence level and chosen method to calculate the confidence interval for each of the four behaviours of interest. Once the confidence interval is calculated, if its lower bound CI_l is above 0.25 or if its upper bound CI_u is below 0.25, the analysis will return that the result for the distance interval under consideration is statistically significant. Otherwise, the result will not be labelled as statistically significant. We indicate the disjunction with `|`, in the same way as in the R syntax.

Algorithm 2: Dyadic behaviour statistical analysis

Input M_D

```

for  $i$  in  $\{1, \dots, n\}$  do
    tot =  $M_D[i][1] + M_D[i][2] + M_D[i][3] + M_D[i][4]$ 
    for  $j$  in  $\{1, \dots, 4\}$  do
        beh_int =  $M_D[i][j]$ 
        CI = binom.confint(beh_int, tot, conf.level = 0.95, method = “exact”)
        if  $CI_l > 0.25 \mid CI_u < 0.25$  then
            return statistically significant
        else
            return not statistically significant

```

2. Extended analysis

For the extended analysis (Algorithm 3), we extract eight behaviour types, by considering also the heading difference and the relative speed. We set the list M_F to keep track of the counts. After the calculation of the usual angles, we evaluate also the heading difference diffH , the pair distance d_{AB} , the individual speed s_A and s_B (as ratio between the distance Δl and time interval Δt) and the proportion of the two individual speeds s_p . If the pair distance d_{AB} lies within a chosen distance interval I_i , then the function f_{cf} classify the pair behaviour type considering all the necessary inputs (here we consider circle segmentation, heading difference and relative speed classification implicitly) and the function u subsequently updates the vector count.

Note that the relative speed classification depends on the speed proportion limits p_l and p_u : given two individuals A and B, the speed proportion limits p_l and p_u are defined such that if the speed proportion s_p (of A with respect to B) is above p_u , then speed of A is considered *greater* than speed of B. If s_p lies

between p_l and p_u , then the speed is considered *similar*, while if the proportion is below p_l , then the speed of B is considered *greater* than the speed of A. Note that the heading difference classification depends on the threshold value θ : in the context of individual headings, we classify a dyad as having a *similar heading* if the absolute value of the heading difference is below θ or above $360 - \theta$, while we classify it as having *the opposite heading* if the difference lies between $180 - \theta$ and $180 + \theta$ degrees. We classify all the other cases as *other*.

Algorithm 3: Extended analysis

Input $\mathcal{T}_A, \mathcal{T}_B, \mathcal{I}$

$M_F = \text{list}()$

for i **in** $\{1, \dots, n\}$ **do**

$M_F[i] = v_0(8)$

$I_{AB} = \mathcal{T}_A \cap \mathcal{T}_B$

for t **in** I_{AB} **do**

$\text{headA} = f(A(t), A(t+1)), \text{headB} = f(B(t), B(t+1))$

$\text{dirAB} = f(A(t), B(t)), \text{dirBA} = f(B(t), A(t))$

$\text{diffA} = |\text{headA} - \text{dirAB}|, \text{diffB} = |\text{headB} - \text{dirBA}|$

$\text{diffH} = |\text{headA} - \text{headB}|$

$d_{AB} = d(A(t), B(t))$

$s_A = \frac{d(A(t), A(t+1))}{\Delta t_A}, s_B = \frac{d(B(t), B(t+1))}{\Delta t_B}$

$s_p = \frac{s_A}{s_B}$

if $\exists i : d_{AB} \in I_i$ **then**

$m_F = f_{cf}(\text{diffA}, \text{diffB}, \text{diffH}, s_p)$

$M_F[i] = u(m_F, M_F[i])$

return M_F

2.1. Extended analysis: behaviours of interest

Table 1 combines the information related to the classified dyadic movement modes, relative speed and individual heading analysis. In the last column of the table, we provide a description of behaviours of interest, used in Section 7.4 of the main paper, including the heading difference classification. Note that we do not distinguish among behaviours of type 3 in the table, but only present examples of the case 3(A,B).

Note that we considered speed and heading difference in the analysis to extract meaningful behaviours (e.g. following, side by side). However, given all the possible combinations, some resulting behaviours might not be meaningful. For example, “both individuals approaching, similar speed, similar heading” is not a possible behaviour, since both individual cannot be moving towards each other and have similar absolute headings.

Table 1: Behaviours of interest extracted via the extended analysis.

Modes	Dyadic behaviour	Speed analysis	Description
1a	Both individuals approach each other	Similar	With opposite individual headings, A and B approaching at a similar speed
1b	Both individuals approach each other	A faster than B	
1c	Both individuals approach each other	B faster than A	
2a	Both individuals retreat from each other	Similar	
2b	Both individuals retreat from each other	A faster than B	
2c	Both individuals retreat from each other	B faster than A	
3a	One individual (A) approaches while the other individual (B) retreats	Similar	With similar individual heading, A following B
3b	One individual (A) approaches while the other individual (B) retreats	A faster than B	With similar individual heading, A chasing B
3c	One individual approaches (A) while the other individual (B) retreats	B faster than A	With similar individual heading, B escaping from A
4a	One individual (A) moves orthogonally, the other (B) approaches	Similar	
4b	One individual moves orthogonally, the other approaches	A faster than B	
4c	One individual moves orthogonally, the other approaches	B faster than A	
5a	One individual moves orthogonally, the other retreats	Similar	
5b	One individual moves orthogonally, the other retreats	A faster than B	
5c	One individual moves orthogonally, the other retreats	B faster than A	
6a	Both individuals move orthogonally	Similar	With similar individual heading, side by side movement
6b	Both individuals move orthogonally	A faster than B	
6c	Both individuals move orthogonally	B faster than A	

3. Simulated data

In this section, we describe the relative-motion, biased random-walk (RM-BRW) models implemented in Numerus Model Builder (NMB) (Getz et al., 2018) and used to generate simulated data. We provide the description of the movement model for individual A of pair (A,B), since the behaviour of individual B is the same as the one of A, just with a different direction (B approaching/retreating from A instead of A approaching/retreating from B).

Given the initial position (x_0, y_0) of individual A, the location coordinates are updated as follows:

$$\begin{aligned} x_{t+1} &= x_t + s_t \cos \theta_t \\ y_{t+1} &= y_t + s_t \sin \theta_t \end{aligned}$$

where s_t is the step length and θ_t is the absolute heading. The step length is drawn from the uniform distribution:

$$s_t \sim \text{UNIFORM}(s_{\min}, s_{\max})$$

while the absolute heading is drawn from different distributions, which are described later.

3.1. Distance-dependent behaviour (attraction and repulsion radial distances)

In the first model, these distributions are distance-dependent with noise introduced using the coefficient $\rho \in [0, 1]$ and attracting and repulsing circles of radii d_R and d_I (Fig. 1):

$$\theta_{t+1} \sim \begin{cases} \text{UNIFORM}(\theta_{A \rightarrow B} - (1 - \rho)\frac{\pi}{2}, \theta_{A \rightarrow B} + (1 - \rho)\frac{\pi}{2}) & \text{if case 1} \\ \text{UNIFORM}(-\theta_{A \rightarrow B} - (1 - \rho)\frac{\pi}{2}, -\theta_{A \rightarrow B} + (1 - \rho)\frac{\pi}{2}) & \text{if case 2} \\ \text{UNIFORM}(-\pi, \pi) & \text{otherwise} \end{cases}$$

where $\theta_{A \rightarrow B}$ is the heading direction from $A(t)$ to $B(t)$, $\rho \in [0, 1]$ and:

- case 1: $d_R < d_{AB} < d_I$ and $\text{UNIFORM}(0,1) < p_{\text{eff}}$
- case 2: $d_{AB} < d_R$ and $\text{UNIFORM}(0,1) < p_{\text{eff}}$

The first case represents approach: the individuals are at a distance between the repulsion distance d_R and the indifference distance d_I , while the second case represents repulsion. These behaviours happen with probability p_{eff} , otherwise the movement is random.

Figure 1: Area of repulsion (red), attraction (blue) and indifference (light orange), depending on d_R and d_I , around one individual. This figure helps illustrating the distance-dependent behaviour described in the model and then captured by our method.

3.2. Time-dependent behaviour

In the second model, the distributions used to draw θ_{t+1} are a function of time. Given the period ω and the functions f_1 and f_2 :

$$f_1(t) = \sin\left(\frac{2\pi t}{\omega}\right)$$

$$f_2(t) = \sin\left(\frac{2\pi t}{\frac{\omega}{2}}\right)$$

the value of the absolute heading is drawn as follow:

$$\theta_{t+1} \sim \begin{cases} \text{UNIFORM}(\theta_{A \rightarrow B} - (1 - \rho)\frac{\pi}{2}, \theta_{A \rightarrow B} + (1 - \rho)\frac{\pi}{2}) & \text{if case 1} \\ \text{UNIFORM}(-\theta_{A \rightarrow B} - (1 - \rho)\frac{\pi}{2}, -\theta_{A \rightarrow B} + (1 - \rho)\frac{\pi}{2}) & \text{if case 2} \\ \text{UNIFORM}(-\pi, \pi) & \text{otherwise} \end{cases}$$

where:

- case 1: $f_1(t) > 0$ and $f_2(t) > 0$
- case 2: $f_1(t) > 0$ and $f_2(t) < 0$

The first case represents A approaching B, the second case A retreating from B while the third case is a random walk, without a preferred direction. In Fig. 2 we show the values of functions f_1 and f_2 , used to control the timing of the various movement behaviours.

Note that the choice of parameters (Table 2) was arbitrary. Other values can be selected, depending on what aspects of the model are being evaluated or tested.

Figure 2: One period of f_1 (black) and 2 periods of f_2 (red). The values of these functions, in particular their sign, are used in the model to govern the time-dependent approach/retreat/indifferent movement behaviours.

Table 2: Parameters used in the simulations

Name	s_{\min}	s_{\max}	ω	ρ	d_I	d_R	p_{eff}
Value	5	6	1440	0.5	60	30	0.5

4. Results

In the results reported here, we used the Euclidean distance to calculate the dyadic distance in units and we scaled the coordinates to be able to use the function `bearing` to calculate the various angles.

4.1. Individual behaviour: individual B

In Fig. 3 we show the results of the individual analysis for individual B.

Figure 3: Barplot for individual B (left). Estimated confidence intervals (CI) for individual B, coloured if statistically significant result (centre) according to the legend (right).

4.2. Dyadic behaviour: pair (A,B)

In Table 3 we present the results of the dyadic behaviour analysis. We indicate behaviours of type 3(A,B) and 3(B,A) using the numbers 3 and 4 respectively. The entry *Total* refers to the total counts of the four behaviours of interest, shown separately in the entry *Count*.

Table 3: Dyadic behaviour results

Pair	Distance interval (units)	Total	Count	Type	Lower CI	Upper CI	Retreat	Approach

4.3. Results for time-dependent RM-BRW model

In this section we show the results of the individual analysis obtained by subdividing our 10-day simulation data depending on the time of the day (first quarter, second quarter and second half of the day), considering dyadic distance below 4000 units (maximum distance: 4002 units). In Fig. 4 we show the results related to the first quarter of the day (first row), the results for the analysis of data from the second quarter of the day (second row) and the results corresponding to the second half of the day (third row). As expected, we observe that in the first quarter of the day the individuals mostly show approach behaviour (in blue) while in the second quarter of the day they show mostly retreat behaviour (in red). In the second half of the day, when the individuals move independently, we observe a balanced mixture of the different behaviour types, without a prevalent one. In Fig. 5 we depict the results of the dyadic analysis, divided depending on the time of the day. Also in this case, the analysis captured the different dyadic behaviour (both approaching, both retreating) for the first 2 quarters of the day, while the second half presents the various dyadic behaviour types.

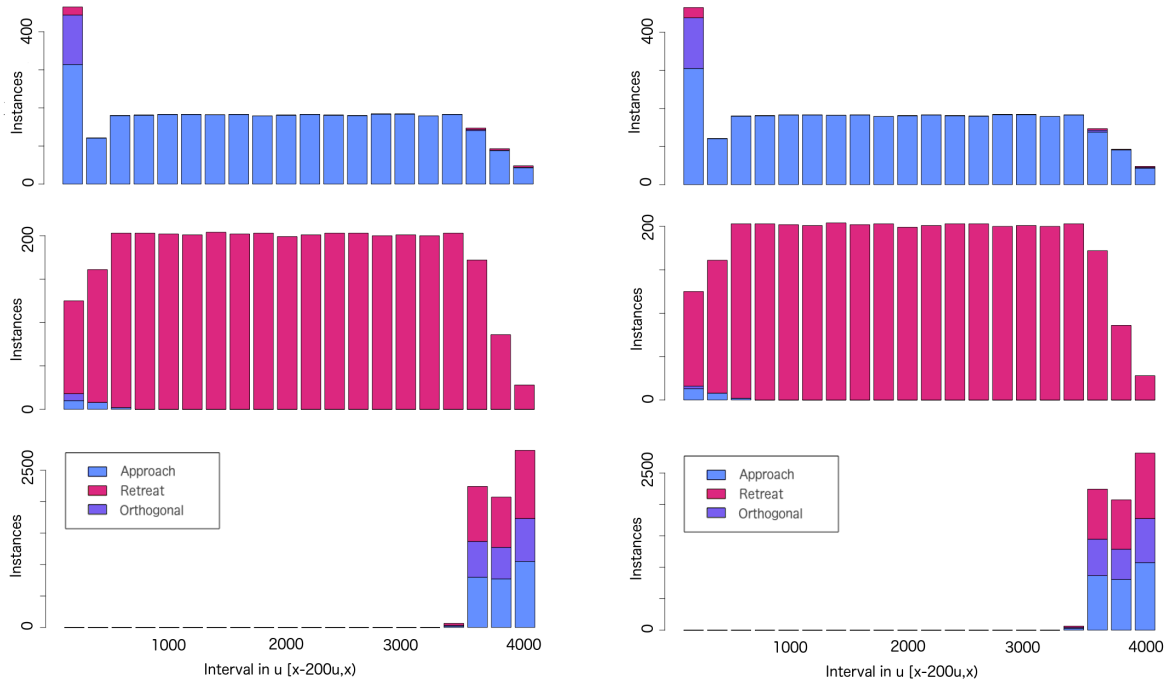

Figure 4: Results of individual analysis for individual A (left) and B (right), for the time-dependent RM-BRW model, for different times of the day. First row: first quarter of the day, second row: second quarter of the day, third row: second half of the day with legend.

Figure 5: Results of dyadic analysis for individual A and B, for the time-dependent RM-BRW model, for different times of the day. From the top: first quarter of the day, second quarter of the day, second half of the day with legend.

5. Empirical data

In Fig. 6 we show the time line of the data collection for each individual and each different data collection frequency. We do not specify the individual names since we focus on showing the data collection time ranges.

Figure 6: Time line of data collection for each individual and for each different frequency.

We now present information from previous work where these data were used, to share more details regarding the data.

- *Information from (Tsalyuk et al., 2019) on 20-min data:* we collected data from 15 elephants with GPS/GSM platform collars (Africa Wildlife Tracking, Pretoria, South Africa), eight female individuals and seven male individuals. Collaring was performed in the central part of Etosha, around Okaukuejo station. Darting and collaring procedures were performed by veterinarians from the Namibian Ministry of Environment and Tourism in compliance with the University of California Berkeley animal care and use protocol (#R217-0511B). Elephants were collared during two periods, October 2008 and July 2009; data were collected for 2.2 months to 4.6 yr (October 2008–March 2014). Location information was recorded in time intervals alternating between 1 min and 19 min. GPS collar accuracy was 3 m, as was confirmed in the field.
- *Information from (Seidel, 2019) on 20-min data:* Before analysis, this trajectory was regularised using the `adehabitatLT` package such that only the first and third fix of each set remained, thereby resulting in relocations every 20 minutes. [...] Regularization was performed using the R function `regularize` (from R package `stmove`) and an expected fix rate of 20 minutes – eliminating every other fix in order to standardise the interval to 20 minutes for future analysis.
- *Information from (Polansky et al., 2015) on 15-min and 30-min data:* Global Positioning System (GPS) satellite and Global Systems for Mobile Communications (GSM) collars: (GSM, 15 min sampling intervals, GPS satellite, 30 min sampling intervals), with a spatial resolution to about 3 m². Fitting and removal of collars were conducted by veterinarians from the Namibian Ministry of Environment and Tourism and in accordance with their best-practice principles. The collared elephants were located in the eastern area of Etosha National Park.

In addition, we removed relocation data in the area of the Okaukuejo station (we believe caused by the GPS collar retrieval). We provide a table for each frequency of data collection (Tables 4-6) before our data cleaning. These tables provide the total number of collected data points and the period of data collection. In addition, they provide the percentage of data points not at the given frequency (15-, 20- or 30-min). For the 15-min frequency data, the most common frequency different than 15-min was 30 minutes. For the 20-min data, it was 40-min, while for 30-min data it was 1-hour.

Table 4: Information regarding 15-min frequency data (all male individuals)

Individual	Total points	15-min	Percentage with different time interval	Period (yyyy-mm-dd)
1	68450	68396	0.076	2009-10-03 - 2011-10-19
2	68409	68356	0.075	2009-10-03 - 2011-10-19
3	67044	65996	1.560	2009-10-03 - 2011-10-19
4	68445	68406	0.054	2009-10-03 - 2011-10-19
5	68573	68532	0.057	2009-10-04 - 2011-10-19
6	68567	68483	0.120	2009-10-04 - 2011-11-01
7	69185	69122	0.088	2009-10-04 - 2011-11-02
8	71465	71415	0.067	2009-10-04 - 2011-11-02
9	70756	70348	0.574	2009-10-05 - 2011-11-17
10	72690	72676	0.017	2009-10-05 - 2011-11-01

Table 5: Information regarding 20-min frequency data

Individual	Sex	Total points	20-min	Percentage with different time interval	Period (yyyy-mm-dd)

5.1. Dyadic behaviour: pair (female,male)

In Table 7 we present the results of the dyadic behaviour analysis for the pair of interest. As before, we indicate behaviours of type 3(A,B) and 3(B,A) with numbers 3 and 4. Statistically significant results are marked using the symbol ✓. Letter A represents the female while letter B represents the male. In Fig. 7 we show the pair distance, colouring each point in time with the colour corresponding to the dyadic behaviour type. Also in this case, we observe a decrease of the pair distance with approach behaviour (indicated in blue), as well as an increase in the pair distance with retreat behaviour (shown in red), as expected.

Figure 7: Distance between the pair, coloured according to the dyadic behaviour type (legend on the right).

5.2. Seasonality

In Tables 8-10 we present the results of the dyadic analysis of the pair of interest looking at data collected during hot-wet, cold-dry and hot-dry season respectively.

Table 7: Results of the dyadic behaviour analysis for pair of interest

Pair	Distance interval (m)	Total	Count	Type	Lower CI	Upper CI	Sign. diff.

6. All pairs of interest

Also in this case, we indicate behaviours of type 3(A,B) and 3(B,A) with numbers 3 and 4. In Tables 11-16 we show the percentage of dyads for which the results were statistically significant (below and above 0.25), for each distance interval. We also illustrate the results depending on the gender of the individuals in the pair, for the 20-min frequency. The data collected at this frequency were the only one providing both male and female time series.

Table 11: Percentage of dyads (15-min frequency data) for which the results were statistically significant (below and above 0.25), for each distance interval.

Distance interval (m)	Type 1 (below)	Type 1 (above)	Type 2 (below)	Type 2 (above)	Type 3 (below)	Type 3 (above)	Type 4 (below)	Type 4 (above)

6.1. 15-min pairs

In this section (Tables 17-25) we provide the results of the pair behaviour statistical analysis for the pairs of interest, for data collected at a 15-min frequency.

Table 17: Left: results for pair (1,2). Right: results for pair (1,3)

Pair	Distance interval (m)	Total	Count	Type	Lower CI	Upper CI	Sign. diff.
1 and 2	[0,30]	77	19	1	0.1256	0.2592	
1 and 2		77	7	2	0.0373	0.1784	✓

6.2. 20-min pairs

In this section (Tables 26-37) we provide the results of the pair behaviour statistical analysis for the pairs of interest, for data collected at a 20-min frequency.

Table 26: Left: results for pair (1,3). Right: results for pair (1,4)

6.3. 30-min pairs

In this section (Tables 38-44) we provide the results of the pair behaviour statistical analysis for the pairs of interest, for data collected at a 30-min frequency.

Table 38: Left: results for pair (1,4). Right: results for pair (1,6)
